

# First Look at Muon Chicane

---

Chris Rogers,  
ASTeC,  
Rutherford Appleton Laboratory

# Overview

- Previously showed a proton absorber can take out protons with momentum  $< \sim 500 \text{ MeV}/c$ 
  - “Shallow” study, needs more work
- Now go on to look at what can be achieved with chicane
  - Aim is to take out all particles with momentum  $> \sim 500 \text{ MeV}/c$
  - Remember that muon momentum acceptance is  $\sim 100 - 400 \text{ MeV}/c$
- Preliminary design
  - Considerations
  - Initial parameter scans
  - Setting up for optimisation

# Chicane concept

- Concept is “pair of double chicanes”
  - High energy particles hit a beam dump
  - Chicane area becomes radioactive
    - Probably part of target remote handling area
  - Beam dump has to handle significant beam energy
- Concentrate here on chicane optics (first look)
  - Propose using bent solenoid optics
  - Good acceptance for this momentum range
    - e.g. used by mu2e experiments
    - e.g. used by 6d cooling channels

# Chicane optics

---

- First try to get reasonable performance for single sign
  - Then start worrying about switch yards, beam dumps, etc
- Model with dipole field superimposed on solenoid field
  - Allows to conveniently change dipole field independent of solenoid
  - Would consider tilted solenoid later
  - Select dipole field to ~return nominal (200 MeV/c) particle to axis
- Three independent parameters
  - Number of coils in the bends
  - Bending angle per coil
  - Solenoid field strength

# First Go

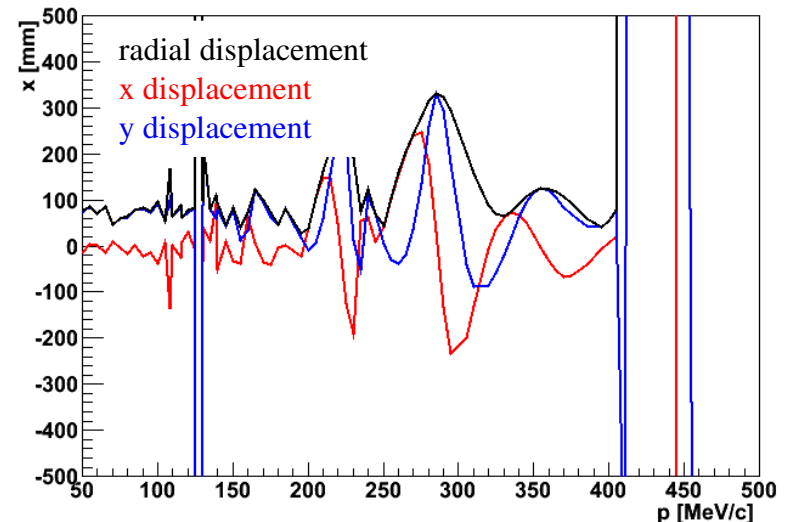

- Try with large aperture solenoids (0.6 m)
  - Displace beam by  $\sim 2$  coil diameters (probably a bit too much)
  - Try:
    - 10 coils per bend with
    - $3^\circ$  bend angle between coils
    - Use baseline 1.5 T  $B_z$
  - Roughly correct momentum acceptance
  - But rather large radial displacement
  - Question tracking accuracy at low p

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 3.0^\circ$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 3.0^\circ \text{ at } z=25900.0$

# Tracking stability

- Low momentum behaviour looks rather like unstable tracking
  - (G4 4th order Runge Kutta)
- No apparent change when I go from 100 mm step size to 1 mm step size
  - $dx \sim 0.1$  mm

$B_z: 1.5$  T  $n_s: 10.0$   $d\theta: 3.0^\circ$  at  $z=25900.0$  100 mm step size

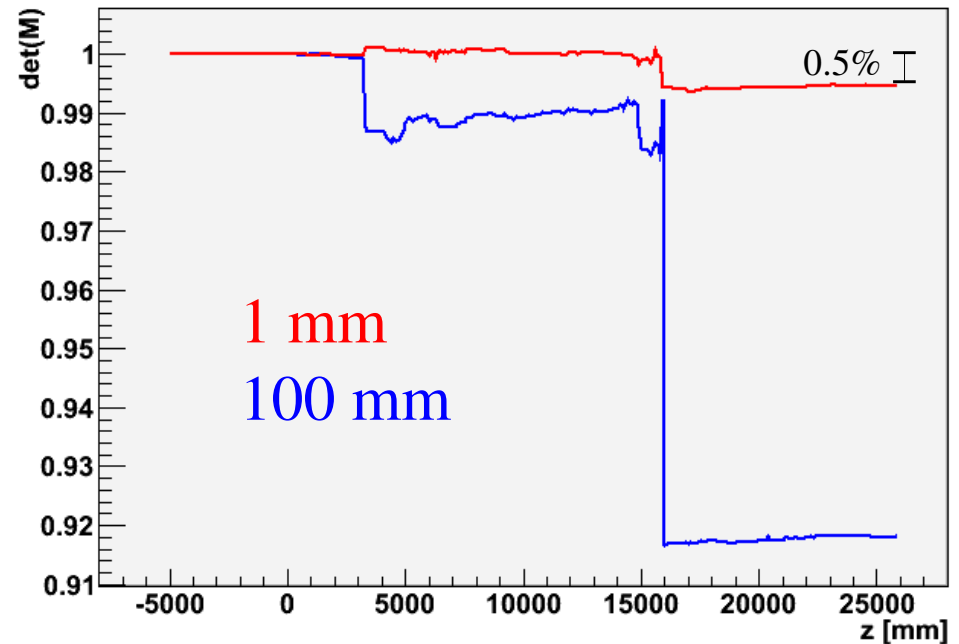

$B_z: 1.5$  T  $n_s: 10.0$   $d\theta: 3.0^\circ$  at  $z=25900.0$  1 mm step size

# Tracking stability (Cont)

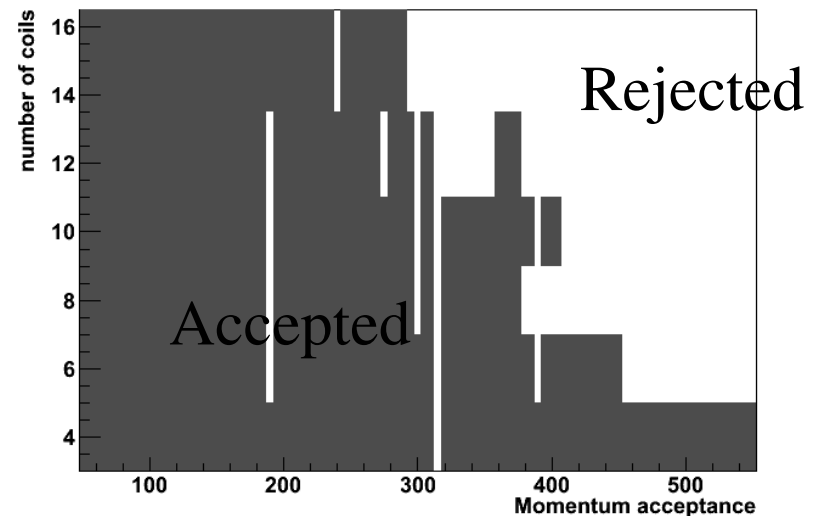

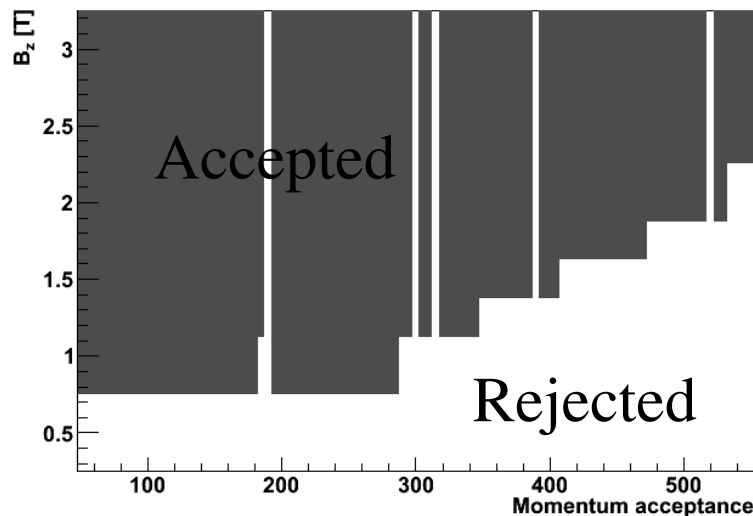

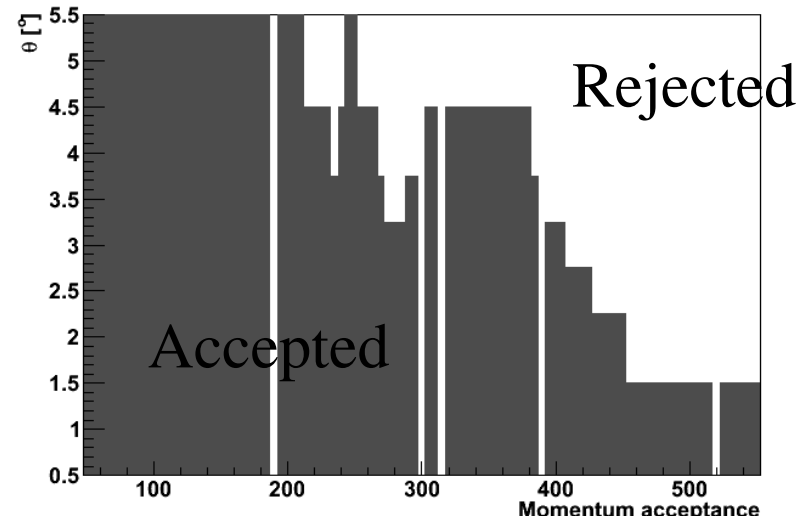

- Calculate 6D transfer matrix
  - Numerical derivative
  - Planes in z
  - 200 MeV/c muons
- Note some variation for 100 mm vs 1 mm steps
  - $\det(M)$  should be  $\approx 1$
- Need some work to understand what causes instability
- For now work with 1 mm step size

# Momentum Acceptance

- How does acceptance vary?
  - Look at transmission of particles initially on-axis
  - Count  $r > 500$  mm as rejected
  - Increasing  $B_z$  improves acceptance
  - Increasing  $d\theta$  worsens acceptance
  - Increasing bend length worsens acceptance

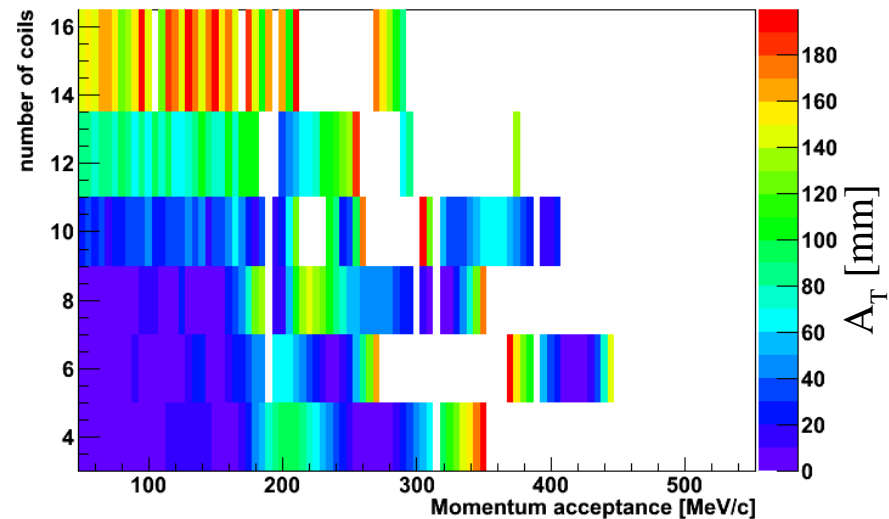

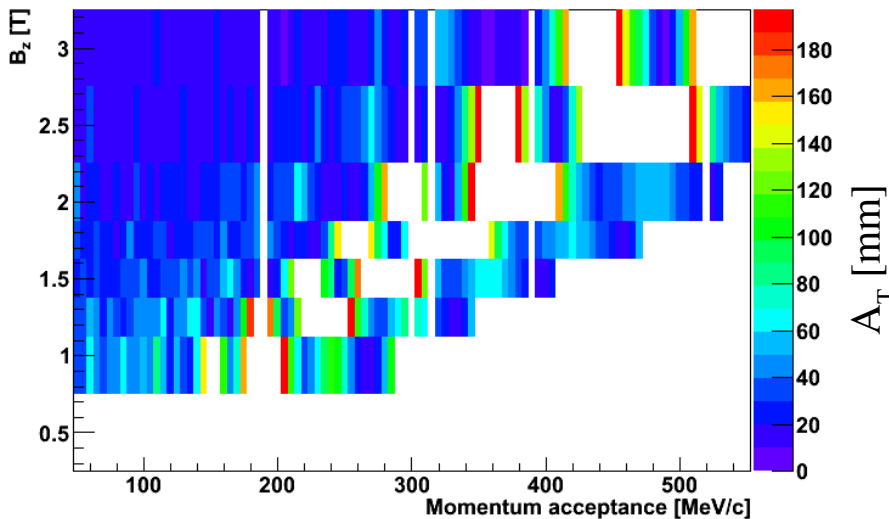

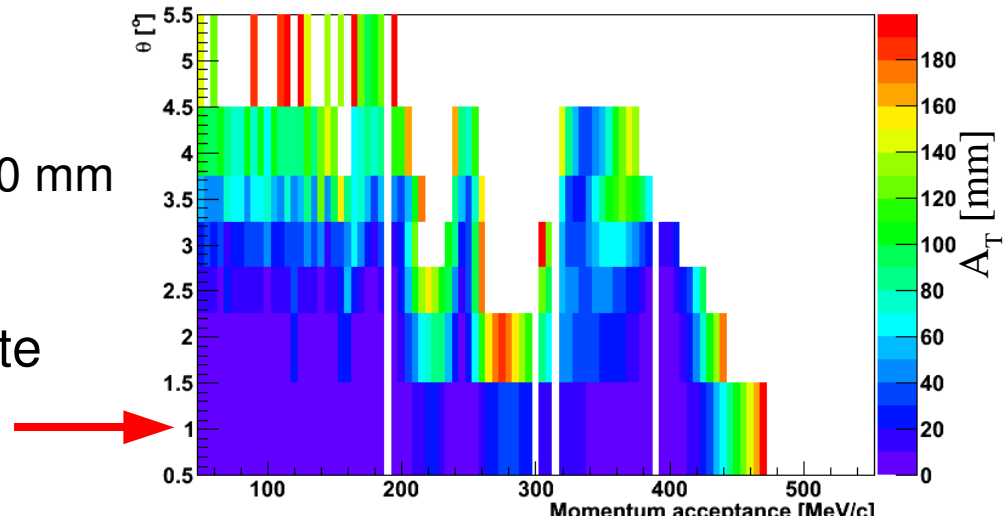

# Amplitude increase vs lattice

- Guestimate emittance growth
  - Look at  $A_T$  of reference trajectory
  - Don't count particles with  $A_T > 200$  mm
  - $\mathcal{E}_T \sim \delta A_T / 4$
- Softer  $d\theta$  looks like promising route
  - Needs more study

# First optimisation

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 1.0^\circ \text{ at } z=25900.0$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 3.0^\circ \text{ at } z=25900.0$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 1.0^\circ$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 3.0^\circ$

# First optimisation

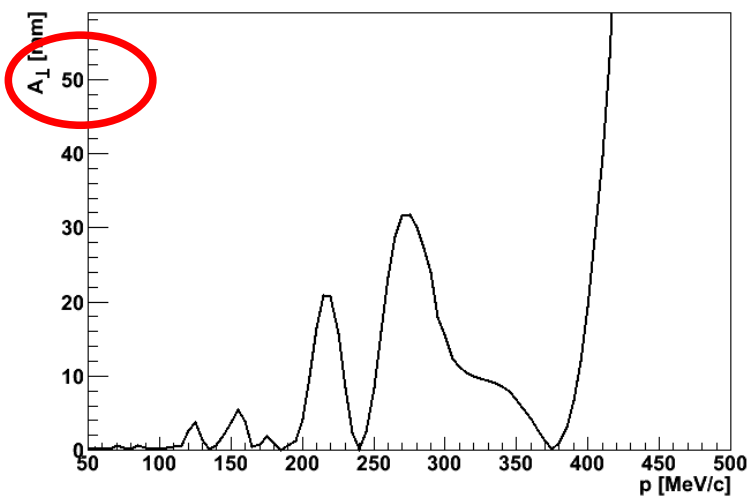

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 1.0^\circ \text{ at } z=25900.0$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 3.0^\circ \text{ at } z=25900.0$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 1.0^\circ \text{ at } z=25900.0$

$B_z: 1.5 \text{ T } n_s: 10.0 \text{ d}\theta: 3.0^\circ \text{ at } z=25900.0$

# Plans

---

- Looks like softening the bending angle gives better transmission
- Some question over tracking accuracy
- Aim is to have a first optics design ready by IDS meeting in January
  - Finish optimisation
- Then look at switch yard, beam dumps, etc
  - Can't dump beam through coils
  - Can't build coils in aperture of -ve polarity beam
  - Integration with proton absorber
  - Integration with transverse collimation
